(57) **ABSTRACT**

Devices and methods for fusing materials using a heating element, where the overall mass to be sealed varies along the length of the seal. According to the invention, the heating element has a different profile in different areas. According to some aspects, the thickness and/or cross section of the heating element is different in different areas so that when a current is passed through the heating element, each area heats to a different degree. In some aspects, the heating element is shaped to conform to the shape of the parts to be fused together. The transition between areas of different thickness or cross-sectional area, or between areas of different shape may be sharply defined. This abrupt transition may be created by machining the heating element to a finished shape rather than bending flat stock to shape.

VARIABLE TEMPERATURE SEAL ELEMENT

FIELD OF THE INVENTION

The subject invention relates to systems and methods for heat sealing. More particularly, the subject invention relates to a sealing element with an engineered profile to allow for targeted areas of different temperature to be contemporaneously created on the same element during the sealing process.

BACKGROUND OF THE INVENTION

A heat sealer is a machine used to seal products and packaging by joining materials using heat. The basic concept is to join two thermoplastic components by applying heat and pressure until the materials melt and flow together, then allowing the components to cool.

There are several different types of heat sealing devices. One particular class of devices, called impulse heat sealers, operates by holding the materials to be joined between jaws that contain one or more resistive heating elements. The materials are held in place by pressure, and heat is applied to the materials by applying an electric current to the heating elements until the materials reach a desired temperature. The heat is maintained until enough time has passed for the materials to flow together adequately. The materials are then allowed to cool, sometimes with the aid of a cooling mechanism, which allows the materials to fuse together.

The strength and quality of the seal that is formed is largely a result of using properly designed components with appropriate materials, and applying correct amounts of temperature and pressure for an appropriate amount of time.

A typical heat sealing application involves fusing two thermoplastic sheets or films to create a bag. In the simplest bags, the sheets are uniform monolayers, and a heat sealer is used to create fused edge seals.

In an application where flat films are fused, the resistive heating elements used in the heat sealer are usually straight pieces of drawn wire or ribbon that are made from a suitable material such as nichrome. The uniform cross-sectional area of such heating elements results in a uniform temperature along the element. This is due to the uniform current density that arises in the uniform resistive element at steady state when current is passed through the element. Such elements function well in simple applications because the materials to be sealed are of a uniform material and thickness.

It is sometimes desirable to seal more complex arrangements of materials. One such application is to seal an object or objects between two sheets such that the sheets form a bag, and such that the object or objects protrude out of the bag through the seal. In these more complex applications, the sheets may be sealed together in places, and sealed to the objects in other places. An example of such a complex application is shown in FIG. 1, where tubes are sealed between two poly sheets to form a medical IV bag with two ports. However this added complexity of construction has a number of implications for creating the seal.

One problem that arises is that unlike the simple case of sealing two flat films, the materials to be sealed are not uniform in mass, thickness, and/or melting or heat-sinking properties. This means that the heating requirements to form a proper seal are different along the length of the seal. For example, in FIG. 1, the portions of the seal which fuse only the two films will require less heat energy to form the seal than the portions which fuse the tubes between the films.

2

This is because the mass of the tubes requires more heat to melt, and also acts as a heat sink, drawing heat away from the films.

Because of these effects, a standard heating element having a uniform cross-sectional area may yield undesirable results when sealing complex arrangements of components. This is because in order to use a standard heating element to form the seal, either the temperature, the time the heat is applied, or both must be increased in order to ensure that a seal is formed in the areas of increased mass.

However, none of these solutions is desirable from a production standpoint. By increasing the heating time, production is slowed and energy costs increase. Further, increased heating time alone may not be adequate in certain circumstances where higher mass parts dissipate heat into the environment rapidly. By increasing the temperature of the element, production speed may be maintained, but the temperature required to seal areas of greater mass may be too great for thinner thermoplastic components. This can result in deformation of the finished product, unreliable seals, degradation of materials, and so forth. The excess heat applied to the thinner regions in order to adequately heat the thicker regions also represents increased energy that is wasted.

Another problem in such applications arises due to the complex shape of the seal. In order to properly apply heat to the surfaces to be joined, the heating element must be shaped to follow the contours of the desired seal, which includes the parts that protrude through the seal. Typically, this is done by simply bending the wire or ribbon of resistive material into the proper shape. However, bending the element in this way can yield inadequate results.

One issue arises if the bending process is not adequate to create a sharp transition between sections of the element having different shapes. This may prevent the heating element from making proper contact with the components to be sealed in the "corners" between profile shapes, thus negatively affecting the bond.

Another issue arises if the bending process at a sharp corner strains the material locally, resulting in a thinning or distortion of the heating element at that point. This may result in an increase in temperature at the corners between shapes due to locally increased current density, which may negatively affect the bond or damage the materials.

Many other complex arrangements of materials are possible, all of which implicate the issues identified above. For example, it may be desirable to seal an article having multiple layers, having gussets in discrete areas, having areas of dissimilar materials, or having fitments or tabs (such as a hang tag) sealed into the article. It may also be desirable to apply a "cut/seal", where an area of the sealer cuts through the materials using added heat and/or pressure.

What is desired, therefore, is a single resistive heat sealing element which possesses the true shape desired, and which also allows for a targeted temperature profile to be created therealong (i.e., higher temperatures in areas of film-to-tube sealing and lower temperatures in areas of film-to-film sealing).

SUMMARY OF THE INVENTION

The inventive concepts described above can be readily adapted for any number of other similar applications. For example, the inventive sealing element can also be used in applications where solid elements (such as, for example, rows of slats, rods, bars, or the like) instead of or in addition

3

to hollow tubes and/or port fittings or the like are to be sealed between layers of film.

Accordingly, it is an object of the present invention to provide a single resistive heat sealing element having an engineered profile. It is a further object of the present invention to provide a resistive heat sealing element.

These and other objectives are achieved by providing a heat sealer for fusing components; having a heating element; an electrical power source connected to the heating element; and, a holder configured to position the components with respect to the heating element; wherein: the heating element comprising a resistive material having a first end and a second end; a first portion of the heating element exhibiting a first electrical resistance; a second portion of the heating element exhibiting a second electrical resistance that is different from the first electrical resistance; and, wherein when electrical current is passed through the heating element, the first portion and the second portion generate different heat levels

In some embodiments, an amount of heat transferred to the components from the first portion is greater than an amount of heat transferred to the components from the second portion.

In some embodiments, the first portion and the second portion are joined at a transition such that the first resistance transitions to the second resistance at the transition.

In some embodiments, the first portion has a first cross-sectional area; and, the second portion has a second cross-sectional area that is greater than the first cross-sectional area. Optionally, the cross-sectional area of at least one of the first portion or the second portion varies along its length. Optionally, a cross-sectional area of the heating element transitions immediately from the first cross-sectional area to the second cross-sectional area at the transition.

In some embodiments, the first portion and the second portion have an equal width; the first portion has a first thickness; and, the second portion has a second thickness that is greater than the first thickness.

In some embodiments, the first portion has a first curvature and the second portion has a second curvature that is different than the first curvature.

In some embodiments, the first curvature transitions to the second curvature at the transition.

In some embodiments, the first portion is curved and the second portion is straight.

In some embodiments, the resistive material conforms to the shape of the components.

In some embodiments, the first portion conforms to a first shape of at least one of the components and the second portion conforms to a shape that is different from the first shape. Optionally, the ratio of the first thickness to the second thickness is 0.012:0.015. Optionally, the width is 0.25 inches, the first thickness is 0.012 inches, and the second thickness is 0.015 inches.

In some embodiments, the heating element is made from a homogeneous resistive material.

Other objectives are achieved by providing a heating element for use in a heat sealing device, comprising a first end and a second end; wherein a first portion of the heating element has a first electrical characteristic; a second portion of the heating element has a second electrical characteristic that is different from the first electrical characteristic; and, the first portion and the second portion are joined at a transition such that the first electrical characteristic transitions to the second electrical characteristic at the transition.

In some embodiments, the electrical characteristic is resistance.

4

In some embodiments, the first portion has a first cross-sectional area; and, the second portion has a second cross-sectional area that is greater than the first cross-sectional area.

In some embodiments, a cross-sectional area of the heating element transitions from the first cross-sectional area to the second cross-sectional area at the transition.

In some embodiments, the cross-sectional area of at least one of the first portion or the second portion varies along its length.

In some embodiments, the first portion and the second portion have an equal width; the first portion has a first thickness; and, the second portion has a second thickness that is greater than the first thickness.

In some embodiments, the first portion has a first curvature and the second portion has a second curvature that is different than the first curvature. Optionally, the first curvature transitions to the second curvature at the transition.

In some embodiments, the first portion is curved and the second portion is straight.

In some embodiments, the resistive material is configured to conform to the shape of the components.

In some embodiments, the first portion conforms to a first shape of at least one of the components and the second portion conforms to a shape that is different from the first shape. Optionally, the ratio of the first thickness to the second thickness is 0.012:0.015. Optionally, the width is 0.25 inches, the first thickness is 0.012 inches, and the second thickness is 0.015 inches.

In some embodiments, the resistive material is homogeneous.

Other objectives are achieved by providing a method of manufacturing a heat sealing device, comprising the steps of: providing a heating element; providing an electrical power source connected to the heating element; and, providing a holder configured to position the components with respect to the heating element; wherein the heating element has a first end and a second end and comprises a resistive material; a first portion of the heating element exhibits a first electrical resistance; a second portion of the heating element exhibits a second electrical resistance; and, wherein when electrical current from the electrical power source is passed through the heating element, the first portion and the second portion generate different heat levels.

In some embodiments, an amount of heat transferred to the components from the first portion is greater than an amount of heat transferred to the components from the second portion.

In some embodiments, the first portion and the second portion are joined at a transition such that the first resistance transitions to the second resistance at the transition.

In some embodiments, the first portion has a first cross-sectional area; and, the second portion has a second cross-sectional area that is greater than the first cross-sectional area.

In some embodiments, the cross-sectional area of at least one of the first portion or the second portion varies along its length.

In some embodiments, a cross-sectional area of the heating element transitions from the first cross-sectional area to the second cross-sectional area at the transition.

In some embodiments, the first portion and the second portion have an equal width; the first portion has a first thickness; and, the second portion has a second thickness that is greater than the first thickness.

In some embodiments, the first portion has a first curvature and the second portion has a second curvature that is

5

different than the first curvature. Optionally, the first curvature transitions to the second curvature at the transition. In some embodiments, the first portion is curved and the second portion is straight.

In some embodiments, the resistive material is conforms to the shape of the components.

In some embodiments, the first portion is configured to conform to a first shape of at least one of the components and the second portion is conforms to a shape that is different from the first shape. Optionally, the ratio of the first thickness to the second thickness is 0.012:0.015. Optionally, the width is 0.25 inches, the first thickness is 0.012 inches, and the second thickness is 0.015 inches.

In some embodiments, the heating element is made from a homogeneous resistive material.

In some embodiments, the heating element is made using an electrical discharge machining process.

In some embodiments, the heating element is made using a process selected from the group of milling, laser beam machining, abrasive jet machining, electrochemical machining, electron beam machining, water jet machining, and 3D printing.

In some embodiments, the heating element is made without bending the resistive material.

Other objectives are achieved by providing A method of fusing materials; comprising the steps of: providing a holder configured to position at least two components together for fusing; providing a heating element configured to apply heat to the at least two components to form a seal; positioning the at least two components using the holder; and, applying an electrical current to the heating element; wherein the heating element has a first end and a second end, and comprises a resistive material; a first portion of the heating element exhibits a first electrical resistance; a second portion of the heating element exhibits a second electrical resistance; and, the first portion and the second portion generate different heat levels.

In some embodiments, the amount of heat transferred to the components from the first portion is greater than an amount of heat transferred to the components from the second portion.

In some embodiments, the first portion and the second portion are joined at a transition such that the first resistance transitions to the second resistance at the transition.

In some embodiments, the first portion has a first cross-sectional area; and, the second portion has a second cross-sectional area that is greater than the first cross-sectional area.

In some embodiments, the cross-sectional area of at least one of the first portion or the second portion varies along its length.

In some embodiments, the cross-sectional area of the heating element transitions from the first cross-sectional area to the second cross-sectional area at the transition.

In some embodiments, the first portion and the second portion have an equal width; the first portion has a first thickness; and, the second portion has a second thickness that is greater than the first thickness.

In some embodiments, the first portion has a first curvature and the second portion has a second curvature that is different than the first curvature. Optionally, the first curvature transitions to the second curvature at the transition.

In some embodiments, the first portion is curved and the second portion is straight.

In some embodiments, the resistive material is configured to conform to the shape of the components.

6

In some embodiments, the first portion is conforms to a first shape of at least one of the components and the second portion conforms to a shape that is different from the first shape. Optionally, the ratio of the first thickness to the second thickness is 0.012:0.015. Optionally, the width is 0.25 inches, the first thickness is 0.012 inches, and the second thickness is 0.015 inches.

In some embodiments, the heating element is made from a homogeneous resistive material.

Other objects of the invention and its particular features and advantages will become more apparent from consideration of the following drawings and accompanying detailed description.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION OF THE INVENTION

FIG. 1 illustrates a portion of a thermoplastic medical IV bag 100 made from thermoplastic sheets 110 and 120, and having tubular ports 130 and 140. Bag 100 is made by fusing ports 130 and 140 between sheets 110 and 120 by forming a heat seal 150. Heat seal 150 has sections 160, 170, 180, 190, and 195. Those having skill in the art will appreciate that this application is not limited to use as an IV bag, and in fact many other uses and applications are possible without departing from the invention.

Heat seal **150** fuses sheets **110** and **120** directly to one another in sections **160**, **170**, and **180**. In sections **190** and **195**, heat seal **150** fuses sheets **110** and **120** to tubes **130** and **140**.

Bag **100** is an example of a typical tube to bag seal construction found in many medical devices, for example. In such arrangements, a simple bag made from two film layers, along with two tubes that act as ports, are provided. The two film layers are arranged with the tubes disposed therebetween, and then peripheries of the film layers are sealed to one another, with the peripheries of the film layers also being sealed to the two tubes to create a fluid-tight pouch having two ports.

FIG. 2 illustrates components of a known impulse heat sealing apparatus for creating a seal **150** as described regarding FIG. 1.

To create seal **150**, heating elements **200** and **200'** are first positioned with respect to bag **100** using a suitable mechanism (not shown), holding tubes **130** and **140** between sheets **110** and **120** by applying pressure in the direction indicated by arrows **250**. Various holding mechanisms are known in the art, including but not limited to clamps, presses, jaws, fixtures, tooling, platens, bars and the like, and those having ordinary skill in the art will appreciate that any of these can be used without departing from the invention. Heat is applied to bag **100** by passing an electric current through elements **200** and **200'**.

Heating elements **200** and **200'** are shaped to accommodate the contours of tubes **130** and **140**, and are made by bending a straight ribbon of resistance material with a constant cross-sectional area into shape, according to known methods. The uniform cross-sectional area of the heating elements results in a uniform temperature along each element during sealing. This is due to the constant current density that arises along the length of the elements when current is applied during sealing.

The desire is to seal tubes **130** and **140** into the edge seal **150** of the bag **100**, but due to the different mass of the film versus the tubes, higher temperatures are required in the specific areas of interface **190**, **195** between the film layers and the tubes, as compared to the temperatures required in the areas **160**, **170**, **180** where the film layers are directly sealed to one another.

Accordingly, in order to fuse tubes **130** and **140** between sheets **110** and **120**, the temperature of heating elements **200** and **200'** must be greater than would be required to fuse sheets **110** and **120** together. This is because the greater mass of tubes **130** and **140** requires additional heat to melt, and also acts as a heat sink.

However, the higher temperatures required to fuse tubes **130** and **140** between sheets **110** and **120** may undesirably deform bag **100**, for instance, by producing shrinkage **280** (FIG. 1) in seal **150** due to overheating of the materials. This shrinkage can result in damage or undesirable puckering **285** (FIG. 1) of bag **100**.

Furthermore, bending heating elements **200**, **200'** to shape can distort or thin the heating elements **200**, **200'** locally, producing a locally decreased cross-sectional area and increased temperatures due to the increased current density at the bends. This can also result in increased heating and damage.

Conversely, the bending may not be adequate to create a sharp transition between the portions of the elements **200**, **200'** corresponding to straight sections **160**, **170**, **180** and curved sections **190**, **195**, resulting in inadequate contact

between elements **200**, **200'** and seal **150**. This inadequate contact can result in reduced heat transfer to seal **150**, and can weaken the seal.

FIG. 3 illustrates an example resistive heat sealing element **300** according to aspects of the invention.

Sealing element **300** may be made from nichrome or any other suitable resistive heating material known in the art. When a sufficient current is passed through sealing element **300**, its temperature will rise in accordance with its material and structural properties.

Sealing element **300** includes straight portions **310**, **320**, and **330**, curved portions **340** and **350**, as well as end portions **360** and **370**. End portions **360** and **370** are shown featuring mounting holes, but these may be omitted or supplemented in some implementations without departing from the invention. Sealing element **300** has a uniform width **400**, although in some implementations the width may vary. Although example sealing element **300** is shown as having a linear shape, those having skill in the art will appreciate that a sealing element may have a serpentine, looped, or circular "donut" shape, such as for producing curved, circular, or other non-linear seals, without departing from the invention.

FIGS. 4 and 5 are alternate views of the sealing element **300** shown in FIG. 3. Unlike known sealing elements **200** and **200'** (FIG. 2), sealing element **300** has different thicknesses at different locations along its length. For example, end portions **360** and **370** each have a thickness **610**; straight portions **310**, **320**, and **330** each have a thickness **620**; and curved portions **340** and **350** each have a thickness **630**.

Thickness **610** is greater than thickness **620**, and thickness **620** is greater than thickness **630**. In this example, the difference in thicknesses of sealing element **300** results in a corresponding difference in cross-sectional areas. This means that when a current is passed through sealing element **300**, thinner sections will exhibit increased heating due to the increased current density in those regions. Here, the end portions **360** and **370** will have the greatest cross-sectional area, and will accordingly exhibit the coolest temperatures. Curved portions **340** and **350** will have the smallest cross-sectional area, and will accordingly exhibit the highest temperatures.

In summary, it can be seen that by varying the thickness of the seal element in desired areas, a single seal element can be used to create desired temperatures in desired areas. More specifically, as can be seen in the drawings, the "flat areas" which are used to create the film-to-film seals are greater in thickness (e.g., 0.015 inches) versus the thickness (e.g., 0.012 inches) of the "curved areas" which are used to create the film-to-tube seals.

Varying the thickness of a heating element in this way can have the advantage of selectively providing increased heating to areas of higher mass and decreased heating to portions of element **300** that are not used for sealing, saving energy costs.

FIG. 6 shows detail view A of the sealing element **300** as shown in FIG. 5, illustrating a clearly defined abrupt transition **600** between end portion **360** and straight portion **310**.

FIG. 7 shows detail view B of the sealing element **300** as shown in FIG. 5, illustrating a clearly defined abrupt transition **700** between straight portion **310** and curved portion **340**.

According to some aspects of the invention, providing clearly defined abrupt transitions **600**, **700** can have the advantage of allowing improved control of heat delivery to different portions of the seal during sealing. Such sharp

transitions are possible by machining rather than bending heating element **300**, as further discussed herein.

It should be noted that in some applications according to the invention, certain transitions (such as transition **600**) may not be required to be sharply defined and abrupt. For example, in applications where the application of heat to the seal **150** begins in straight portion **310** and does not overlap transition **600**, a sharp drop in temperature, and accordingly thickness, may not be critical.

In an example implementation, a sealing element (not shown) with a similar profile to element **300**, having a width of 0.25", end thicknesses of 0.030" straight section thicknesses of 0.015" and curve thicknesses of 0.012" was analyzed. It was found that an electrical current applied to this sealing element (not shown) could result in a temperature range of over 100 degrees Fahrenheit between the straight and curved sections. It will be clear to those having skill in the art that altering these dimensions can result in greater or lesser ranges of temperatures.

This controllability of temperature along the length of a sealing element can have the advantage of improving seals by enabling more precise heat delivery to regions having different melting and/or heat-sink properties.

FIGS. **8** and **9** illustrate sealing element **300** as shown in FIGS. **3-8**, wherein element **300** is shown as machined from a block of a resistive heating element material **900**, according to aspects of the invention. In some implementations, material **900** is nichrome or stainless steel, although other suitable materials will be evident to those having skill in the art.

As discussed earlier, it is difficult to achieve sharp transitions between portions of a sealing element having different shapes using typical methods of bending the element to shape. This is because bending produces strain in the material which can thin or distort the element, resulting in uneven heating which can damage the parts to be sealed.

In order to avoid this problem, heating element **300** is machined from a block of resistive material **900** to create the desired shape, thicknesses, and abrupt transitions between areas of different thickness and areas of different shape.

In some implementations, sealing element **300** is machined from block **900** using an electrical discharge machining (EDM) process. However, other methods of machining are possible within the scope of invention, including but not limited to milling, laser beam machining, abrasive jet machining, electrochemical machining, electron beam machining, and water jet machining.

Machining the sealing element in this way can have the advantage of enabling sharp transitions to be created between regions of the sealing element having different thicknesses and/or different shapes.

It should be noted that according to some aspects of the invention, the machining process is not necessary, so long as the profile of the sealing element includes regions having different cross-sectional areas. According to other aspects of the invention, a sealing element may be machined from a block of resistive heating material and further processed by bending. An example of an application where a combination of machining and bending may be appropriate would be in a circumstance where a sharp transition between shapes or thicknesses is required in one portion of the heating element but not in another.

FIG. **10** illustrates a method **1000** of creating a sealing element according to aspects of the invention.

In step **1010**, a block of resistive heating material is provided. The block of resistive heating material may be

made from nichrome, stainless steel, or any other suitable resistive heating material known in the art.

In step **1020**, a band of material is cut from the block of resistive heating material such that the band has a varying profile. The band of material forms a heating element that may be configured as discussed herein according to any aspect of the invention.

FIG. **11** illustrates a method **1100** of creating a heat sealing device according to aspects of the invention.

In step **1110**, a holding device is provided, which is configured to apply pressure to at least two components. The holding device is configured such that the components can be held in a desired position for fusing. Various holding devices are known in the art, including but not limited to clamps, presses, jaws, fixtures, tooling, platens, bars and the like, and those having ordinary skill in the art will appreciate that any of these can be used without departing from the invention.

In step **1120**, a resistive heating element is installed into the holding device and configured to heat the components when a current is applied to the resistive heating element for a desired amount of time and then allowed to cool. The resistive heating element may be configured as discussed herein according to any aspect of the invention.

FIG. **12** illustrates a method **1200** of fusing parts according to aspects of the invention.

In step **1210**, a heat sealing device is provided having a resistive heating element which has a shape designed to correspond with the contours of a particular arrangement of parts to be fused. The resistive heating element may be configured as discussed herein according to any aspect of the invention.

In step **1220**, components desired to be fused are inserted into the heat sealing device.

In step **1230**, electrical current is applied to the resistive heating element such that heat is applied to the components.

In step **1240**, the current is switched off, and the components are allowed to cool.

In step **1250**, the components are removed from the heat sealing device.

FIG. **13** shows another example heat sealing application where an inflatable cushion **1300** includes a molded thermoplastic port **1310** sealed between two monolayer films. Port **1310** interacts with the seal in a similar fashion to the tubes shown in FIGS. **1** and **2**, except that thermoplastic port **1310** has a different shape and mass distribution. Those having skill in the art will appreciate that this application is not limited to use as an inflatable cushion, and in fact many other uses and applications are possible without departing from the invention.

FIG. **14** illustrates a sealing element **1400** having a shape adapted for the application shown in FIG. **13**. Sealing element **1400** has end portions **1410** and **1420**, straight portions **1430** and **1440**, and as a shaped portion **1450**. End portions **1410** and **1420** are shown featuring mounting holes, but these may be omitted or supplemented in some implementations without departing from the invention. Sealing element **1400** has a uniform width **1460**, although in some implementations the width may vary.

FIG. **15** is an alternate view of the sealing element **1400** shown in FIG. **14**.

Sealing element **1400** has different thicknesses at different locations along its length. For example, end portions **1410** and **1420** each have a thickness **1510**; straight portions **1430** and **1440** each have a thickness **1520**; and shaped portion **1450** has a thickness **1530**.

11

Thickness 1510 is greater than thickness 1520, and thickness 1520 is greater than thickness 1530. The variation in thicknesses of sealing element 1400 results in a corresponding variation in cross-sectional area. This means that when a current is passed through sealing element 1400, sections having a lesser thickness will exhibit increased heating due to the increased current density in those regions. Here, end portions 1410 and 1420 will have the greatest cross-sectional area, and will accordingly exhibit the coolest temperatures. Shaped portion 1450 will have the smallest cross-sectional area, and will accordingly exhibit the highest temperatures.

Varying the thickness of a heating element in this way can have the advantage of selectively providing increased heating to areas of higher mass and decreased heating to portions of element 1400 that are not used for sealing, saving energy costs.

FIG. 16 shows a detail view C of the sealing element 1400 as shown in FIG. 16, illustrating the transition 1600 between end portion 1430 and straight portion 1450.

Providing a sharp transition 1600 between thickness 1520 and thickness 1530 can have the advantage of providing improved control of heat delivery to different portions of the seal during sealing.

Port 1310 (FIG. 13) has a profile that varies continuously between thinner and thicker portions. Accordingly, in some implementations (not shown) the thickness of shaped portion 1450 of sealing element 1400 may vary in a continuous fashion to correspond to the continuously varying profile of port 1310. This can have the added advantage of even more precisely controlling the application of heat to areas of a part having heat-sink properties that vary continuously along the length of the seal.

Although the invention has been described with reference to a particular arrangement of parts, features and the like, these are not intended to exhaust all possible arrangements or features, and indeed many modifications and variations will be ascertainable to those of skill in the art.

What is claimed is:

1. A heat sealer for fusing components; comprising:
 - a heating element;
 - an electrical power source connected to the heating element; and,
 - a holder configured to position the components with respect to the heating element;
 wherein:
 - said heating element comprising a resistive material having a first end and a second end;
 - a first portion of said heating element exhibiting a first electrical resistance;
 - a second portion of said heating element exhibiting a second electrical resistance that is different from the first electrical resistance; and,
 - wherein the electrical power source causes electrical current to pass through said heating element, such that the first portion and the second portion generate different heat levels due to the first portion and the second portion having different electrical resistances.
2. The heat sealer of claim 1, wherein an amount of heat transferred to the components from the first portion is greater than an amount of heat transferred to the components from the second portion.
3. The heat sealer of claim 1, wherein said first portion and said second portion are joined at a transition such that the first resistance transitions to the second resistance at the transition.

12

4. The heat sealer of claim 1, wherein:

said first portion has a first cross-sectional area; and, said second portion has a second cross-sectional area that is greater than the first cross-sectional area.

5. The heat sealer of claim 4, wherein the cross-sectional area of at least one of said first portion or said second portion varies along its length.

6. The heat sealer of claim 4, wherein a cross-sectional area of the heating element transitions immediately from the first cross-sectional area to the second cross-sectional area at the transition.

7. The heat sealer of claim 1, wherein:

said first portion and said second portion have an equal width;

said first portion has a first thickness; and, said second portion has a second thickness that is greater than said first thickness.

8. The heat sealer of claim 1, wherein:

said first portion has a first curvature and

said second portion has a second curvature that is different than the first curvature.

9. The heat sealer of claim 8, wherein the first curvature transitions to the second curvature at the transition.

10. The heat sealer of claim 1, wherein said first portion is curved and said second portion is straight.

11. The heat sealer of claim 1, wherein said resistive material conforms to the shape of the components.

12. The heat sealer of claim 1, wherein said first portion conforms to a first shape of at least one of the components and said second portion conforms to a shape that is different from the first shape.

13. The heat sealer of claim 7, wherein the ratio of the first thickness to the second thickness is 0.012:0.015.

14. The heat sealer of claim 7, wherein the width is 0.25 inches, the first thickness is 0.012 inches, and the second thickness is 0.015 inches.

15. The heat sealer of claim 1, wherein said heating element is made from a homogeneous resistive material.

16. The heat sealer of claim 1, wherein the first portion and the second portion have a common longitudinal axis that is transverse to the first cross-sectional area and the second cross-sectional area.

17. The heat sealer of claim 1, wherein the first portion and the second portion have different longitudinal axes.

18. The heat sealer of claim 1, wherein a first resistive coating is applied to a first area on the element.

19. The heat sealer of claim 18, wherein a second resistive coating exhibiting a resistance different from the first resistive coating is applied to a second area on the element.

20. A heating element for use in a heat sealing device, comprising:

a first end and a second end;

wherein:

a first portion of said heating element has a first electrical characteristic;

a second portion of said heating element has a second electrical characteristic that is different from the first electrical characteristic;

said first portion and said second portion are joined at a transition such that the first electrical characteristic transitions to the second electrical characteristic at the transition; and

electrical current passing through said heating element causes the first portion and the second portion to generate different heat levels due to the first portion and the second portion having different electrical characteristics.

13

21. The heating element of claim 20, wherein the electrical characteristic is resistance.

22. The heating element of claim 20, wherein:
said first portion has a first cross-sectional area; and,
said second portion has a second cross-sectional area that
is greater than the first cross-sectional area. 5

23. The heating element of claim 22, wherein a cross-sectional area of the heating element transitions from the first cross-sectional area to the second cross-sectional area at the transition.

24. The heating element of claim 22, wherein the cross-sectional area of at least one of said first portion or said second portion varies along its length. 10

25. The heating element of claim 20, wherein:
said first portion and said second portion have an equal
width;
said first portion has a first thickness; and,
said second portion has a second thickness that is greater
than said first thickness. 15

26. The heating element of claim 20, wherein:
said first portion has a first curvature and
said second portion has a second curvature that is different
than the first curvature. 20

27. The heating element of claim 26, wherein the first curvature transitions to the second curvature at the transition.

14

28. The heating element of claim 20, wherein said first portion is curved and said second portion is straight.

29. The heating element of claim 20, wherein said heating element is configured to conform to the shape of components being heat sealed.

30. The heating element of claim 29, wherein said first portion conforms to a first shape of at least one of the components and said second portion conforms to a shape that is different from the first shape.

31. The heating element of claim 25, wherein the ratio of the first thickness to the second thickness is 0.012:0.015.

32. The heating element of claim 25, wherein the width is 0.25 inches, the first thickness is 0.012 inches, and the second thickness is 0.015 inches.

33. The heating element of claim 20, wherein said heating element is made from a homogeneous material.

34. The heating element of claim 20, wherein a first resistive coating is applied to a first area on the heating element.

35. The heating element of claim 34, wherein a second resistive coating exhibiting a resistance different from the first resistive coating is applied to a second area on the heating element.
